

RB-Tree Augmentation

- Augment x with **Size(x)**, where
 - $\text{Size}(x)$ = size of subtree rooted at x
 - $\text{Size}(\text{NIL}) = 0$

OS-Select

OS-SELECT(x,i) //page 304

// Select the node with rank i

// in the subtree rooted at x

1. $r \leftarrow \text{size}[\text{left}[x]]+1$
2. if $i = r$ then
3. return x
4. elseif $i < r$ then
5. return OS-SELECT (left[x], i)
6. else return OS-SELECT (right[x], $i-r$)

Time Complexity $O(\log n)$

OS-Rank

OS-RANK(x,y)

// Different from text (recursive version)

// Find the rank of y in the subtree rooted at x

1 $r = \text{size}[\text{left}[y]] + 1$

2 if $x = y$ then return r

3 else if ($\text{key}[x] < \text{key}[y]$) then

4 return OS-RANK(x, left[y])

5 else return $r + \text{OS-RANK}(x, \text{right}[y])$

Time Complexity $O(\log n)$

Augmenting RB-Trees

Theorem 14.1, page 309

Let f be a field that augments a red-black tree T with n nodes, and $f(x)$ can be computed using only the information in nodes x , $\text{left}[x]$, and $\text{right}[x]$, including $f[\text{left}[x]]$ and $f[\text{right}[x]]$.

Then, we can maintain $f(x)$ during insertion and deletion without asymptotically affecting the $O(\lg n)$ performance of these operations.

For example,

$$\text{size}[x] = \text{size}[\text{left}[x]] + \text{size}[\text{right}[x]] + 1$$

$$\text{rank}[x] = ?$$

Examples of augmenting information for RB-Trees

- Parent
- Height
- Any associative function on all previous values or all succeeding values.
- Next
- Previous

Interval Trees

- **Need:** Dynamic data structure to store time intervals
- **Application:** Maintain schedule for set of seminars
- **Operations:** Insert, Delete
- Every interval j has: $low[j]$, $high[j]$
- **Data Structure:**
 - Augment RB-Tree so that it can store intervals.
 - Ordering based on what key? low values? $high$ values? $(high+low)/2$ values? $(high-low)$ values?
 - Note that insert and delete are still efficient.
- **New Operation:** Search (find any overlapping interval)
 - Problem with Search!

Augmented Information

- *low, high, max*
- $\text{max}[x]$ = rightmost high value of all intervals in subtree rooted at x
- The value $\text{max}[x]$ of each node can be written as:
$$\text{max}[x] = \text{Max} \{ \text{high}[\text{int}[x]], \text{max}[\text{left}[x]], \text{max}[\text{right}[x]] \}$$
- Therefore it can be maintained efficiently under insertions and deletions

Interval-Search

INTERVAL-SEARCH (T, j)

// finds an interval in tree T that overlaps interval j,

// else return NIL.

1. $x = \text{root}[T]$
2. while $x \neq \text{NIL}$ and j does not overlap $\text{int}[x]$ do
3. if $\text{left}[x] \neq \text{NIL}$ and $\text{max}[\text{left}[x]] \geq \text{low}[j]$ then
4. $x = \text{left}[x]$
5. else $x = \text{right}[x]$
6. return x

Time Complexity $O(\log n)$
