

Gene Expression

- Process of transcription and/or translation of a gene is called **gene expression**.
- Every cell of an organism has the same genetic material, but different genes are **expressed** at different times.
- Patterns of gene expression in a cell is indicative of its state.

Hybridization

- If two complementary strands of DNA or mRNA are brought together under the right experimental conditions they will **hybridize**.
- **A hybridizes to B** \Rightarrow
 - **A** is reverse complementary to **B**, or
 - **A** is reverse complementary to a subsequence of **B**.
- It is possible to experimentally verify whether **A** hybridizes to **B**, by **labeling A** or **B** with a radioactive or fluorescent tag, followed by excitation by laser.

Measuring gene expression

- Gene expression for a single gene can be measured by extracting mRNA from the cell and doing a simple **hybridization** experiment.
- Given a sample of cells, gene expression for every gene can be measured using a single microarray experiment.

Microarray/DNA chip technology

- High-throughput method to study gene expression of thousands of genes simultaneously.
- Many applications:
 - Genetic disorders & Mutation/polymorphism detection
 - Study of disease subtypes
 - Drug discovery & toxicology studies
 - Pathogen analysis
 - Differing expressions over time, between tissues, between drugs, across disease states

Microarray Data

Gene	Expression Level
Gene1	
Gene2	
Gene3	
...	

Microarray/DNA chips (Simplified)

- Construct **probes** corresponding to reverse complements of genes of interest.
- Microscopic quantities of probes placed on solid surfaces at defined spots on the chip.
- Extract mRNA from sample cells and **label** them.
- Apply labeled sample (mRNA extracted from cells) to every spot, and allow hybridization.
- Wash off unhybridized material.
- Use optical detector to measure amount of fluorescence from each spot.

Gene Chips

Affymetrix DNA chip schematic

www.affymetrix.com

What's on the slide?

RNA fragments with fluorescent tags from sample to be tested

Shining a laser light at GeneChip® array causes tagged DNA fragments that hybridized to glow

DNA Chips & Images

Microarrays: competing technologies

- Affymetrix & Synteni/Stanford
- Differ in:
 - method to place DNA: Spotting vs. photolithography
 - Length of probe
 - Complete sequence vs. series of fragments

How to compare 2 cell samples with Two-Color Microarrays?

- mRNA from sample 1 is extracted and labeled with a **red fluorescent** dye.
- mRNA from sample 2 is extracted and labeled with a **green fluorescent** dye.
- Mix the samples and apply it to every spot on the microarray. Hybridize sample mixture to probes.
- Use optical detector to measure the amount of **green** and **red** fluorescence at each spot.

Cy3 Probe

Simultaneous hybridization

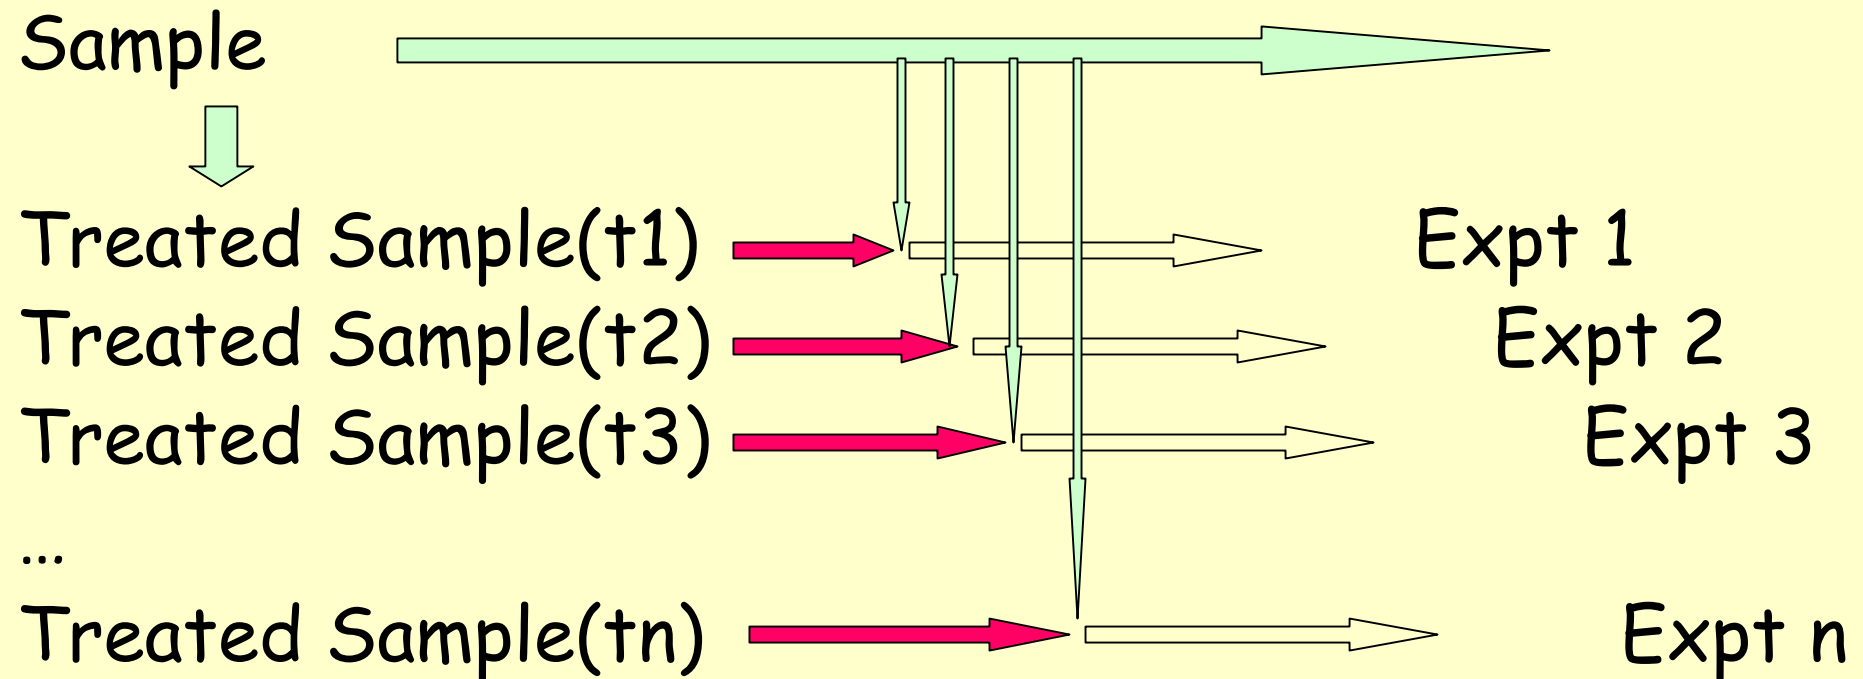

Normalization

Data extraction

Scanning

Study effect of treatment over time

Sources of Variations & Errors

- Variations in cells/individuals.
- Variations in mRNA extraction, isolation, introduction of dye, variation in dye incorporation, dye interference.
- Variations in probe concentration, probe amounts, substrate surface characteristics
- Variations in hybridization conditions and kinetics
- Variations in optical measurements, spot misalignments, discretization effects, noise due to scanner lens and laser irregularities
- Cross-hybridization of sequences with high sequence identity.
- Limit of factor 2 in precision of results.

Need to Normalize data

Types of bias/variation

- Intensity & Range
 - Variation changes with intensity. Larger variation at lower end.
- Spatial
 - Spot location changes expression
- Plate
 - Printing plate changes expression

http://www.arabidopsis.org/info/2010_projects/comp_proj/AFGC/RevisedAFGC/Friday/index.htm

Clustering

- Clustering is a general method to study patterns in gene expressions.
- Several known methods:
 - Hierarchical Clustering (Bottom-Up Approach)
 - K-means Clustering (Top-Down Approach)
 - Self-Organizing Maps (SOM)

Hierarchical Clustering: Example

A Dendrogram

Hierarchical Clustering [Johnson, SC, 1967]

- Given n points in \mathbb{R}^d , compute the distance between every pair of points
- While (not done)
 - Pick closest pair of points s_i and s_j and make them part of the same cluster.
 - Replace the pair by an average of the two s_{ij}

Try the applet at:

<http://www.cs.mcgill.ca/~papou/#applet>

Distance Metrics

- For clustering, define a distance function:
 - Euclidean distance metrics

$$D_k(X, Y) = \left[\sum_{i=1}^d (X_i - Y_i)^k \right]^{1/k}$$

k=2: Euclidean Distance

- Pearson correlation coefficient

$$\rho_{xy} = \frac{1}{d} \sum_{i=1}^d \left(\frac{X_i - \bar{X}}{\sigma_x} \right) \left(\frac{Y_i - \bar{Y}}{\sigma_y} \right)$$

$-1 \leq \rho_{xy} \leq 1$

EXHIBIT 3.4 Joint Probability Model for the Ratings of Two People

Clustering of gene expressions

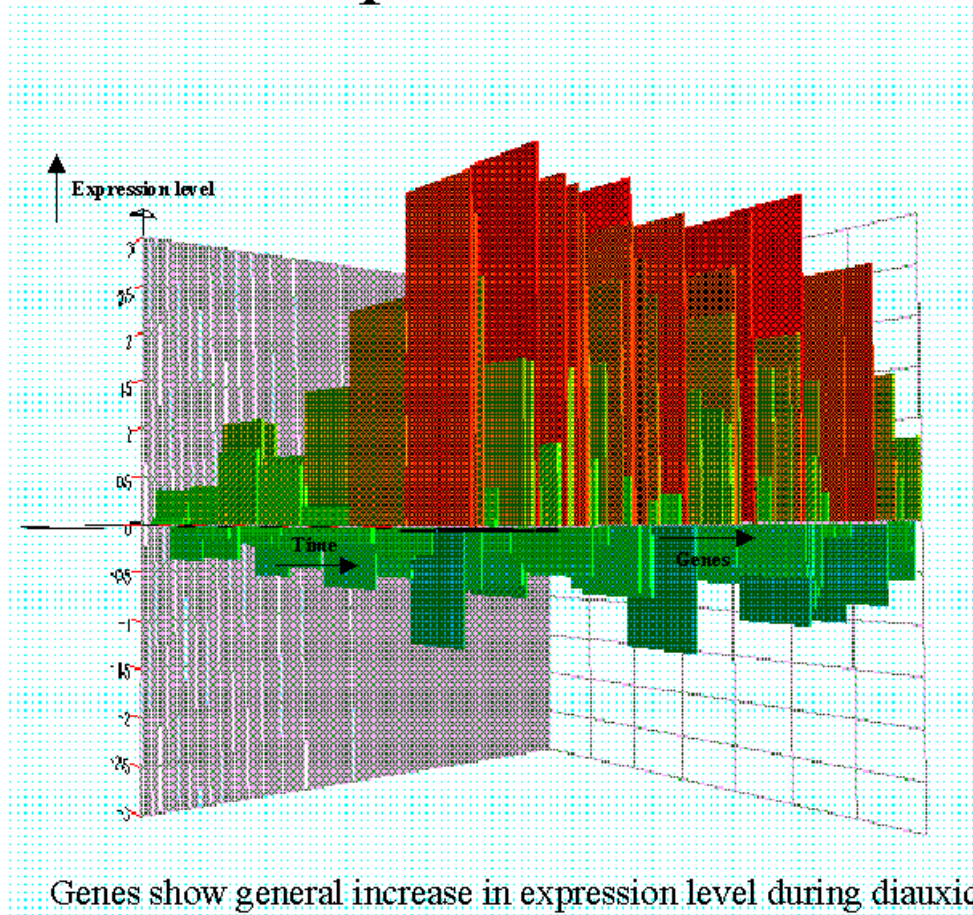

- Represent each gene as a vector or a point in d -space where d is the number of arrays or experiments being analyzed.

Clustering Random vs. Biological Data

From Eisen MB, et al, PNAS 1998 95(25):14863-8

Expression Profiles for Respiration Genes

Genes show general increase in expression level during diauxic shift

Expression Profiles for Fermentation Genes

Bar two exceptions, genes show general decrease in expression level during diauxic shift

Observations

- ◆ As glucose was depleted - Marked change in the global pattern of gene expression
- ◆ ~50% of differentially expressed genes have unknown function
- ◆ Genes with similar expression profiles had common promoters
- ◆ Expression patterns observed match those observed in other types of experiments

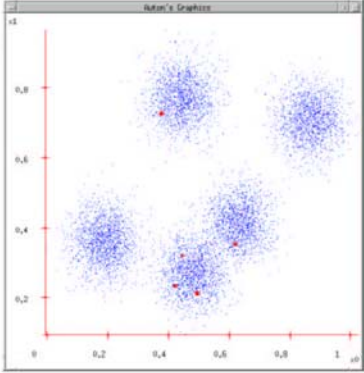

K-Means Clustering: Example

Example from Andrew Moore's tutorial on Clustering.

Start

K-means

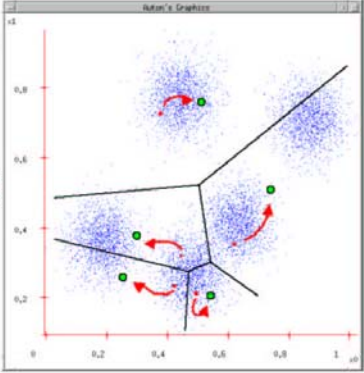

1. Ask user how many clusters they'd like. (e.g. $k=5$)
2. Randomly guess k cluster Center locations

Copyright © 2001, Andrew W. Moore
K-means and Hierarchical Clustering: Slide 7

K-means

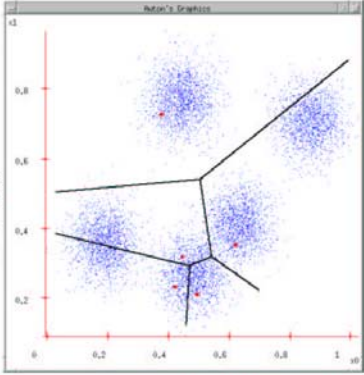

1. Ask user how many clusters they'd like. (e.g. $k=5$)
2. Randomly guess k cluster Center locations
3. Each datapoint finds out which Center it's closest to.
4. Each Center finds the centroid of the points it owns

Copyright © 2001, Andrew W. Moore
K-means and Hierarchical Clustering: Slide 8

K-means

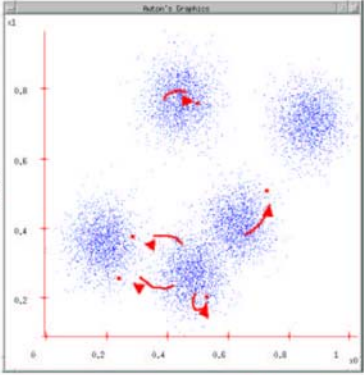

1. Ask user how many clusters they'd like. (e.g. $k=5$)
2. Randomly guess k cluster Center locations
3. Each datapoint finds out which Center it's closest to. (Thus each Center "owns" a set of datapoints)

Start

End

K-Means Clustering [McQueen '67]

Repeat

- Start with randomly chosen cluster centers
- Assign points to give greatest increase in score
- Recompute cluster centers
- Reassign points

until (no changes)

Try the applet at: <http://www.cs.mcgill.ca/~bonnef/project.html>

Comparisons

- Hierarchical clustering
 - Number of clusters not preset.
 - Complete hierarchy of clusters
 - Not very robust, not very efficient.
- K-Means
 - Need definition of a **mean**. Categorical data?
 - More efficient and often finds optimum clustering.

Functionally related genes behave similarly across experiments

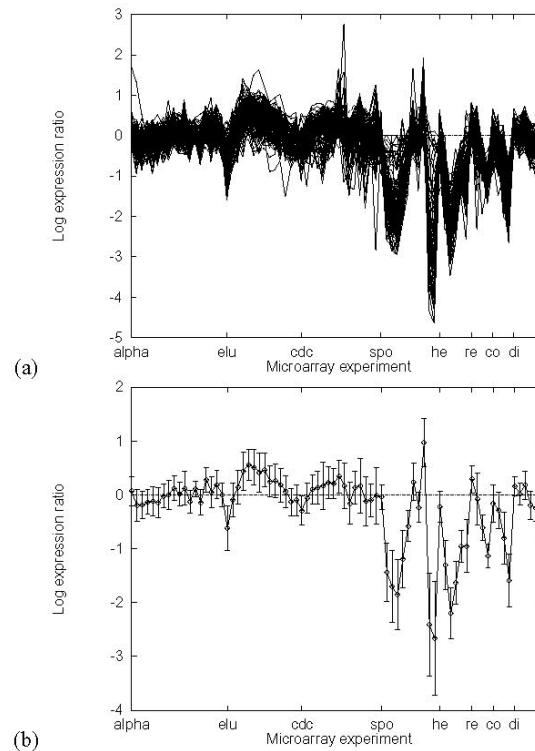

Figure 1: **Expression profiles of the cytoplasmic ribosomal proteins.** Figure (a) shows the expression profiles from the data in [Eisen et al., 1998] of 121 cytoplasmic ribosomal proteins, as classified by MYGD [MYGD, 1999]. The logarithm of the expression ratio is plotted as a function of DNA microarray experiment. Ticks along the X-axis represent the beginnings of experimental series. They are, from left to right, cell division cycle after synchronization with α factor arrest (alpha), cell division cycle after synchronization by centrifugal elutriation (elu), cell division cycle measured using a temperature sensitive *cdc15* mutant (cdc), sporulation (spo), heat shock (he), reducing shock (re), cold shock (co), and diauxic shift (di). Sporulation is the generation of a yeast spore by meiosis. Diauxic shift is the shift from anaerobic (fermentation) to aerobic (respiration) metabolism. The medium starts rich in glucose, and yeast cells ferment, producing ethanol. When the glucose is used up, they switch to ethanol as a source for carbon. Heat, cold, and reducing shock are various ways to stress the yeast cell. Figure (b) shows the average, plus or minus one standard deviation, of the data in Figure (a).

Self-Organizing Maps [Kohonen]

- Kind of neural network.
- Clusters data and find complex relationships between clusters.
- Helps reduce the dimensionality of the data.
- Map of 1 or 2 dimensions produced.
- Unsupervised Clustering
- Like K-Means, except for visualization

SOM Architectures

- 2-D Grid
- 3-D Grid
- Hexagonal Grid

SOM Algorithm

- Select SOM architecture, and initialize weight vectors and other parameters.
- **While** (stopping condition not satisfied) **do**
for each input point x
 - winning node q has weight vector **closest** to x .
 - **Update** weight vector of q and its **neighbors**.
 - **Reduce neighborhood size** and **learning rate**.

SOM Algorithm Details

- **Distance** between x and weight vector: $\|x - w_i\|$
- **Winning node**: $q(x) = \min_i \|x - w_i\|$
- **Weight update** function (for neighbors):

$$w_i(k+1) = w_i(k) + \mu(k, x, i)[x(k) - w_i(k)]$$

- **Learning rate**:

$$\mu(k, x, i) = \eta_0(k) \exp\left(\frac{-\|r_i - r_{q(x)}\|^2}{\sigma^2}\right)$$

World Bank Statistics

- Data: World Bank statistics of countries in 1992.
- 39 indicators considered e.g., health, nutrition, educational services, etc.
- The complex joint effect of these factors can be visualized by organizing the countries using the self-organizing map.

World Poverty PCA

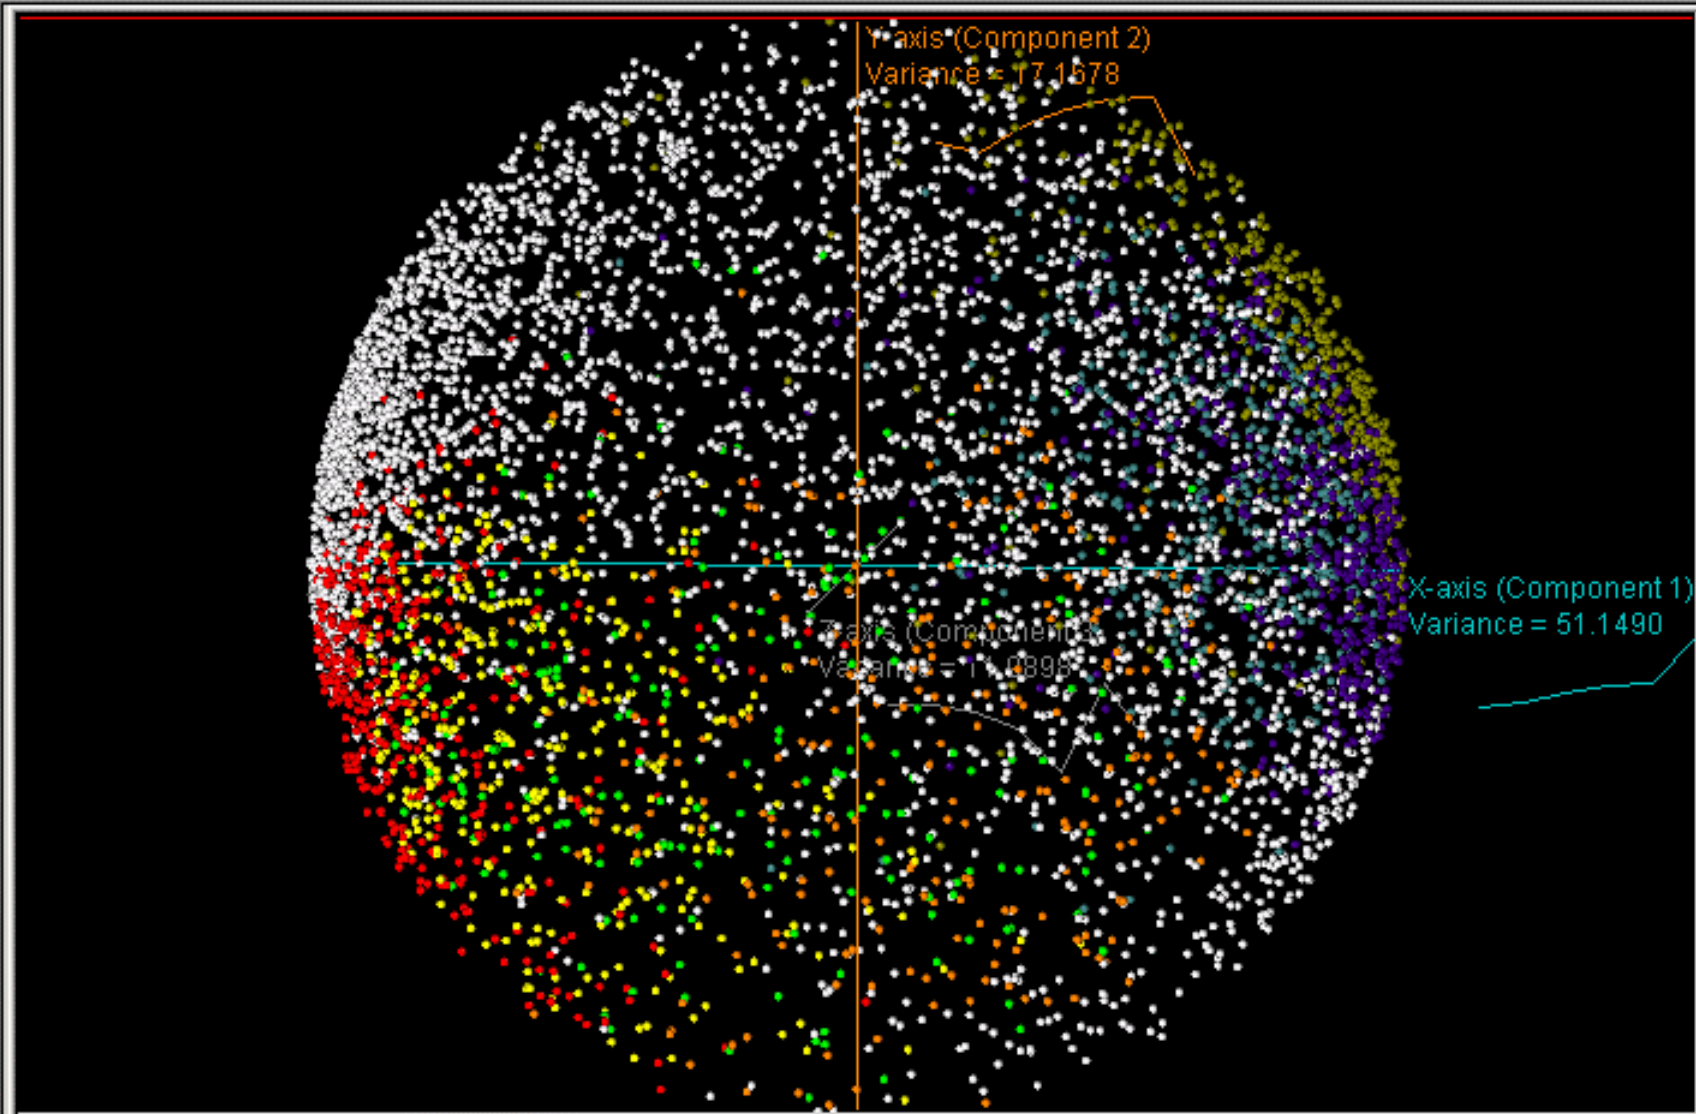

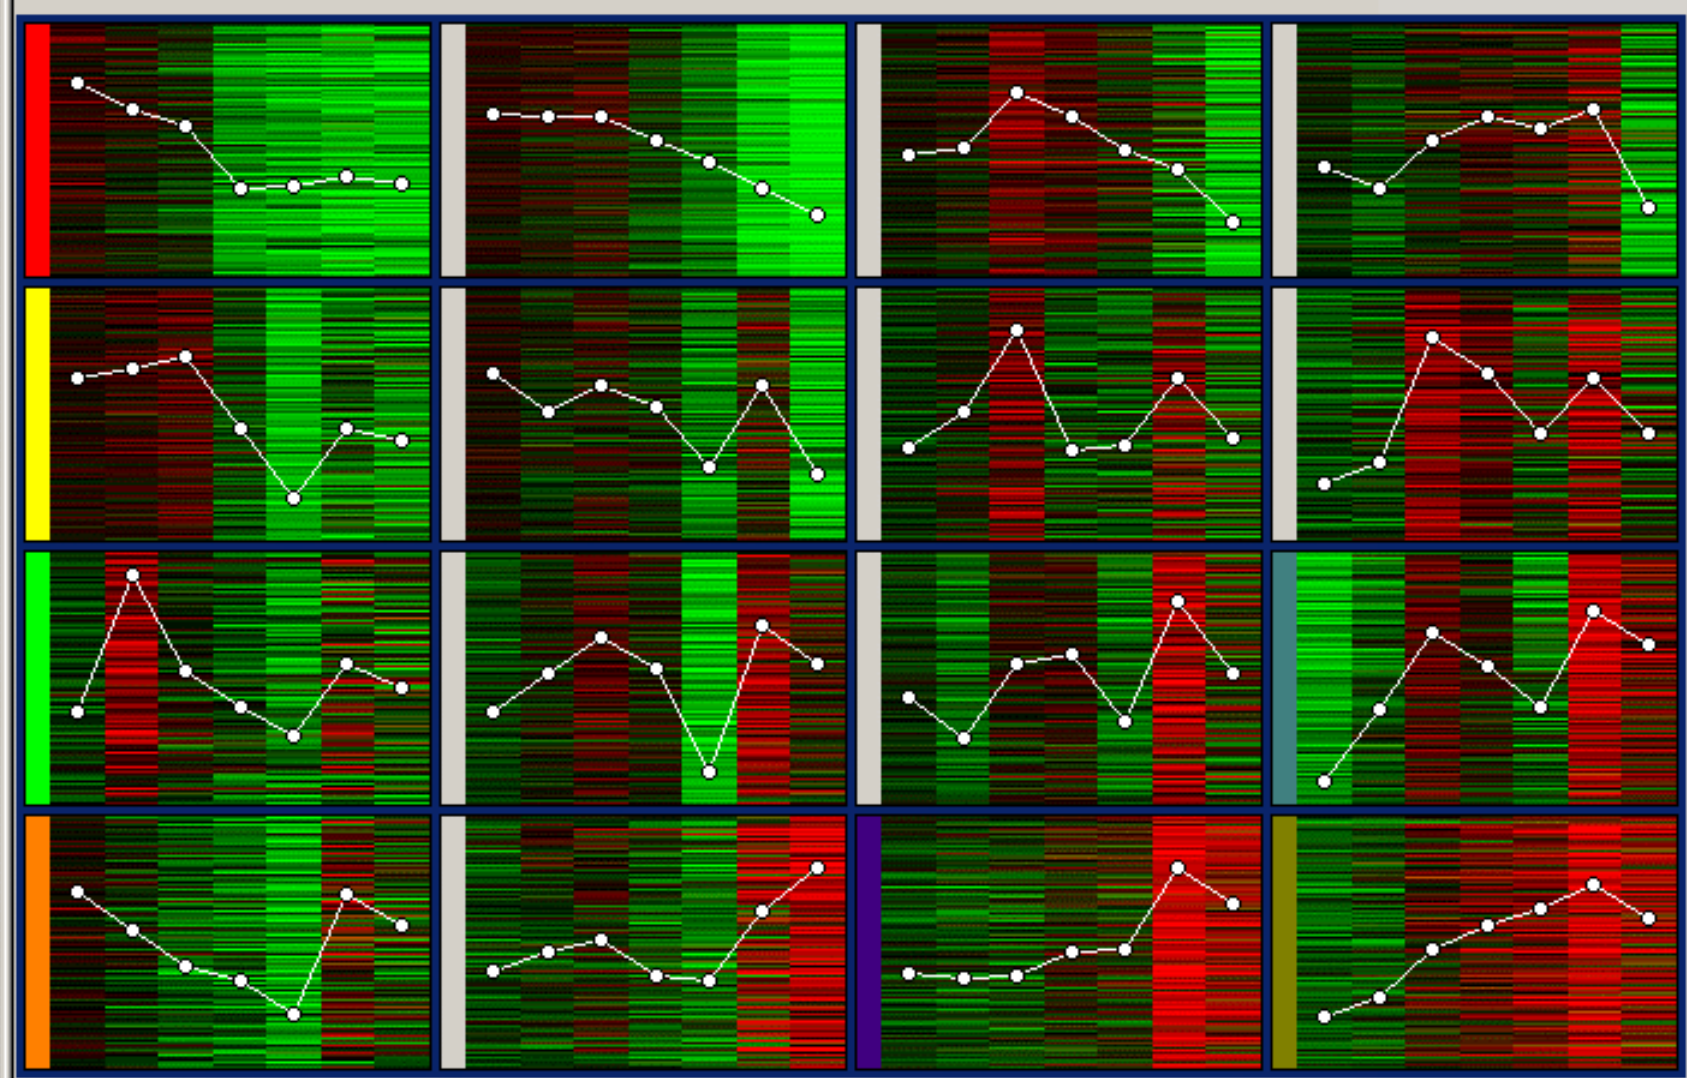

World Poverty SOM

World Poverty Map

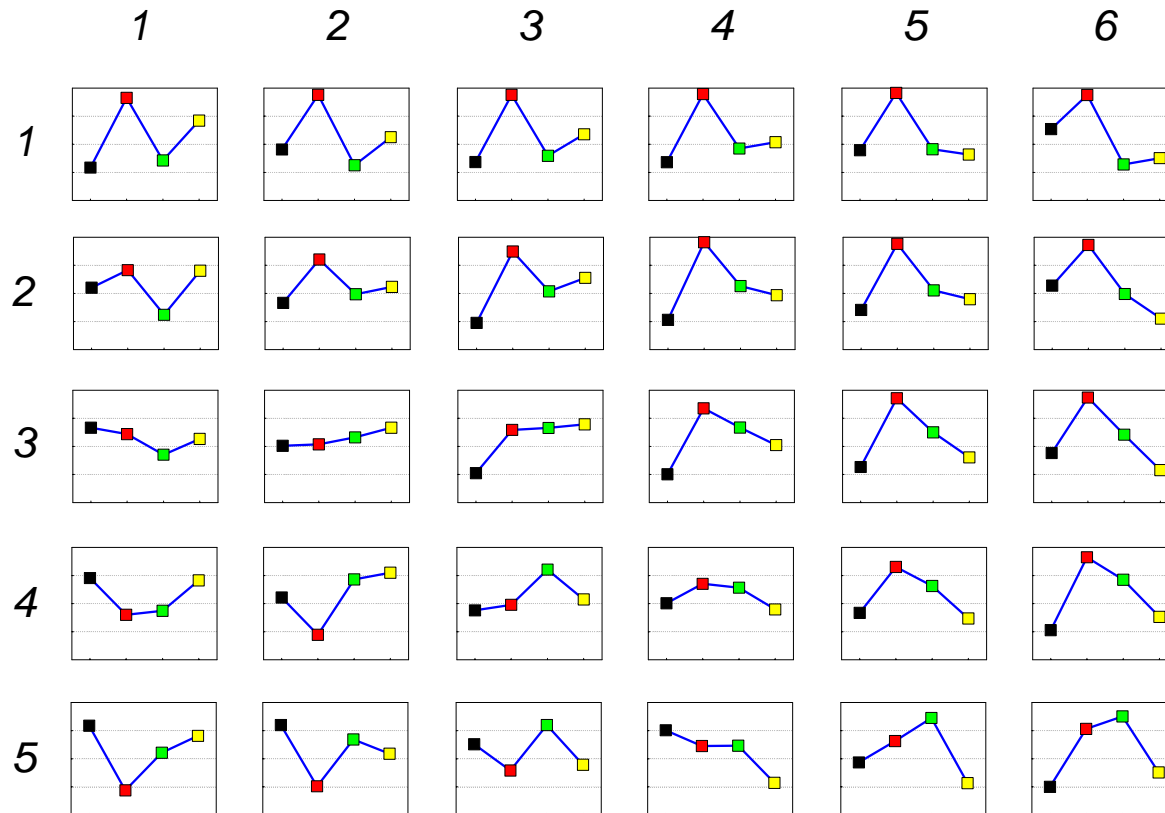

Summary Graph **Visualizations** Results Parameters Report

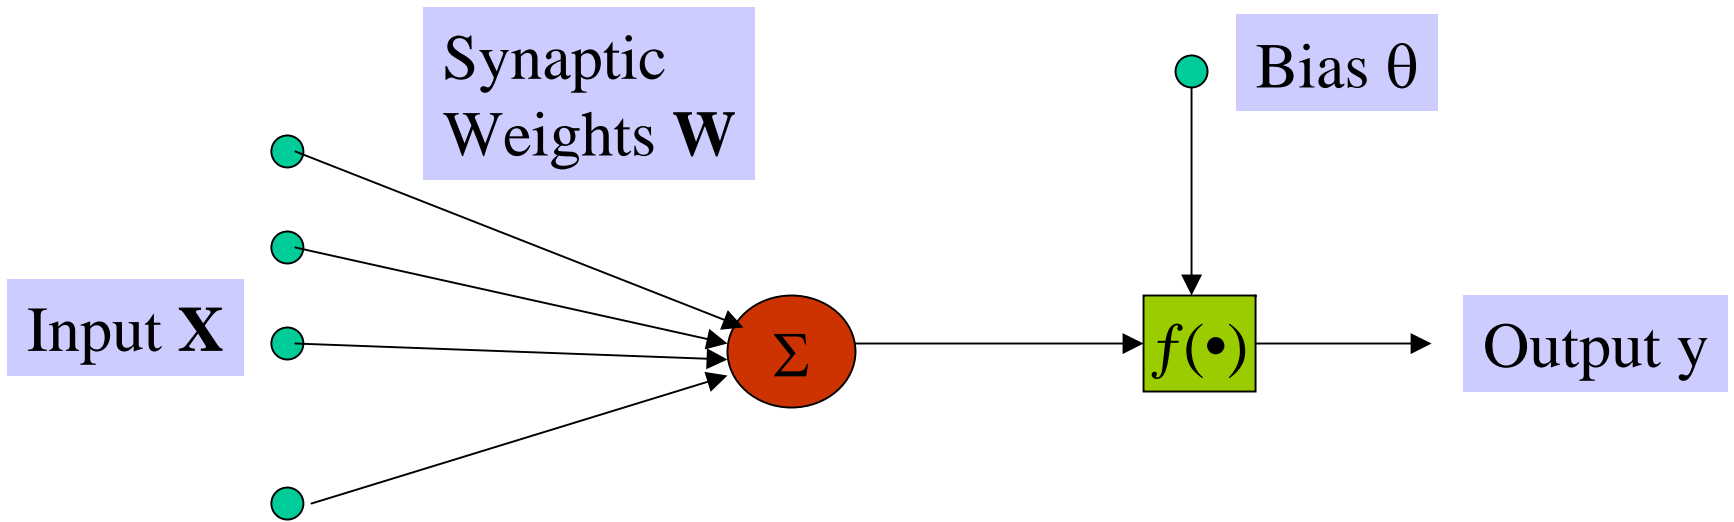

Viewing SOM Clusters on PCA axes

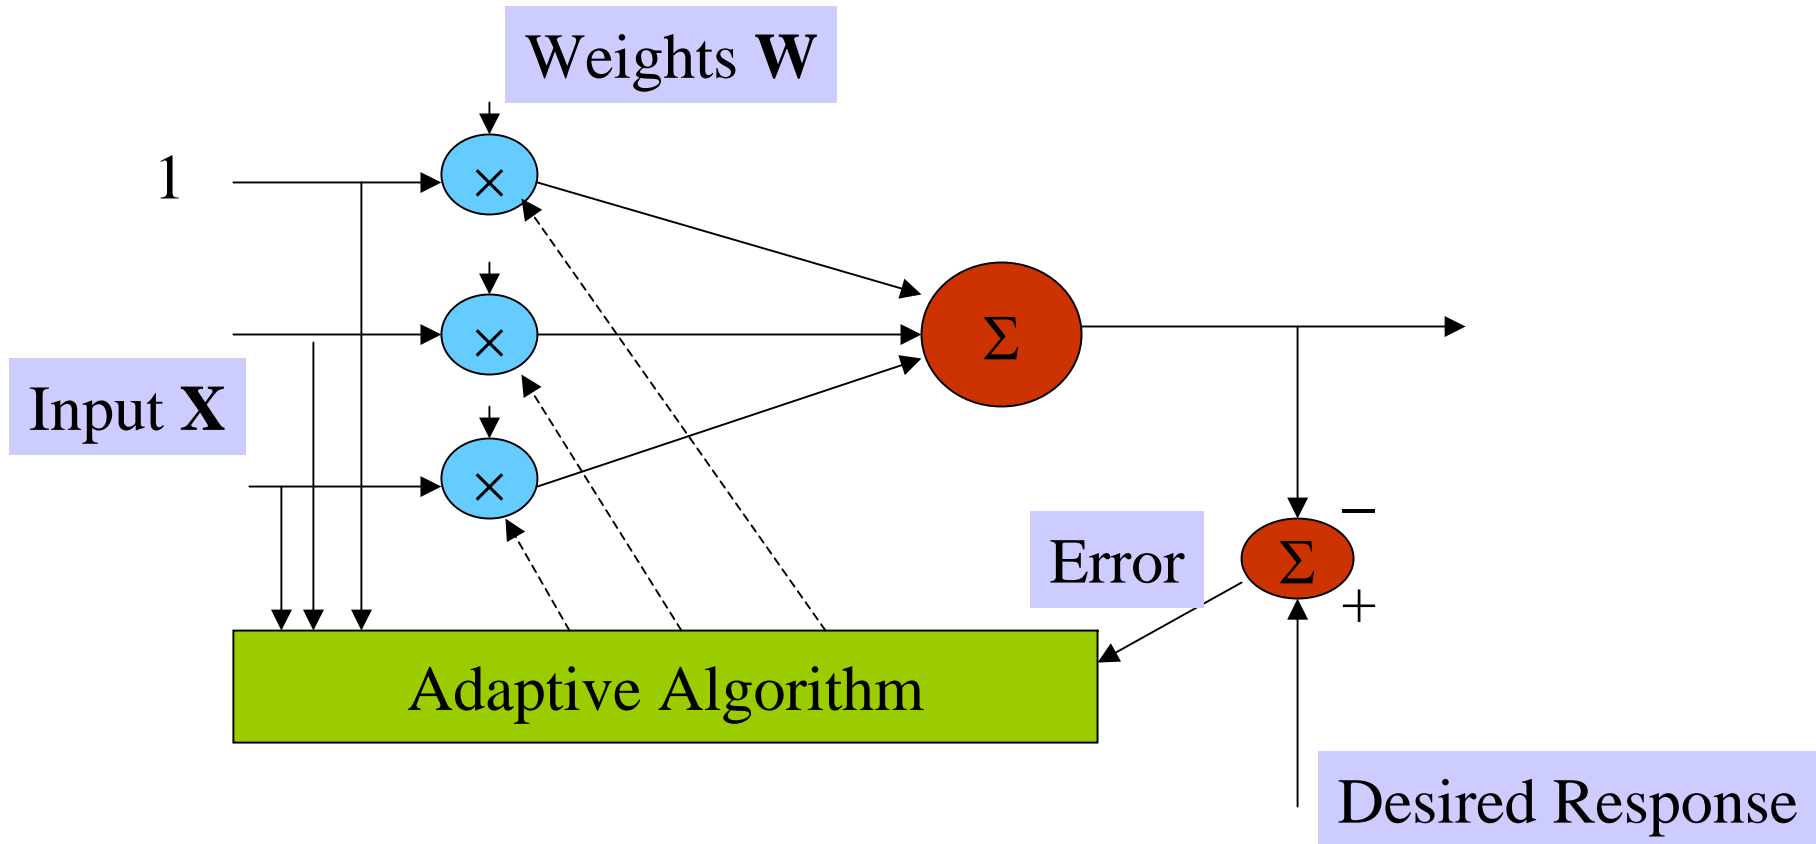

SOM Example [Xiao-ru He]

Neural Networks

Learning NN

Types of NNs

- Recurrent NN
- Feed-forward NN
- Layered

Other issues

- Hidden layers possible
- Different activation functions possible

Application: Secondary Structure Prediction

Support Vector Machines

- Supervised Statistical Learning Method for:
 - Classification
 - Regression
- Simplest Version:
 - **Training:** Present series of labeled examples (e.g., gene expressions of tumor vs. normal cells)
 - **Prediction:** Predict labels of new examples.

Learning Problems

SVM – Binary Classification

- Partition feature space with a surface.
- Surface is implied by a subset of the training points (vectors) near it. These vectors are referred to as **Support Vectors**.
- Efficient with high-dimensional data.
- Solid statistical theory
- Subsume several other methods.

Learning Problems

- Binary Classification
- Multi-class classification
- Regression

Table 2: Comparison of error rates for various classification methods. Classes are as described in Table 1. The methods are the radial basis function SVM, the SVMs using the scaled dot product kernel raised to the first, second and third power, Parzen windows, Fisher's linear discriminant, and the two decision tree learners, C4.5 and MOC1. The next five columns are the false positive, false negative, true positive and true negative rates summed over three cross-validation splits, followed by the cost, which is the number of false positives plus twice the number of false negatives. These five columns are repeated twice, first using the threshold learned from the training set, and then using the threshold that minimizes the cost on the test set. The threshold optimization is not possible for the decision tree methods, since they do not produce ranked results.

Table 4: Comparison of SVM performance using various kernels. For each of the MYGD classifications, SVMs were trained using four different kernel functions on five different random three-fold splits of the data, training on two-thirds and testing on the remaining third. The first column contains the class, as described in Table 1. The second column contains the kernel function, as described in Table 2. The next five columns contain the threshold-optimized cost (i.e., the number of false positives plus twice the number of false negatives) for each of the five random three-fold splits. The final column is the total cost across all five splits.

Family	Gene	Locus	Error	Description
TCA	YPR001W	CIT3	FN	mitochondrial citrate synthase
	YOR142W	LSC1	FN	α subunit of succinyl-CoA ligase
	YNR001C	CIT1	FN	mitochondrial citrate synthase
	YLR174W	IDP2	FN	isocitrate dehydrogenase
	YIL125W	KGD1	FN	α -ketoglutarate dehydrogenase
	YDR148C	KGD2	FN	component of α -ketoglutarate dehydrogenase complex in mitochondria
	YDL066W	IDP1	FN	mitochondrial form of isocitrate dehydrogenase
Resp	YBL015W	ACH1	FP	acetyl CoA hydrolase
	YPR191W	QCR2	FN	ubiquinol cytochrome-c reductase core protein 2
	YPL271W	ATP15	FN	ATP synthase epsilon subunit
	YPL262W	FUM1	FP	fumarase
	YML120C	NDI1	FP	mitochondrial NADH ubiquinone 6 oxidoreductase
	YKL085W	MDH1	FP	mitochondrial malate dehydrogenase
	YDL067C	COX9	FN	subunit VIIa of cytochrome c oxidase
Ribo	YPL037C	EGD1	FP	β subunit of the nascent-polypeptide-associated complex (NAC)
	YLR406C	RPL31B	FN	ribosomal protein L31B (L34B) (YL28)
	YLR075W	RPL10	FP	ribosomal protein L10
	YAL003W	EFB1	FP	translation elongation factor EF-1 β
Prot	YHR027C	RPN1	FN	subunit of 26S proteasome (PA700 subunit)
	YGR270W	YTA7	FN	member of CDC48/PAS1/SEC18 family of ATPases
	YGR048W	UFD1	FP	ubiquitin fusion degradation protein
	YDR069C	DOA4	FN	ubiquitin isopeptidase
	YDL020C	RPN4	FN	involved in ubiquitin degradation pathway
Hist	YOL012C	HTA3	FN	histone-related protein
	YKL049C	CSE4	FN	required for proper kinetochore function

Table 6: Consistently misclassified genes. The table lists all 25 genes that are consistently misclassified by SVMs trained using the MYGD classifications listed in Table 1. Two types of errors are included: a false positive (FP) occurs when the SVM includes the gene in the given class but the MYGD classification does not; a false negative (FN) occurs when the SVM does not include the gene in the given class but the MYGD classification does.

Kernel	DF	Feature	FP	FN	TP	TN

Table 1: Error rates for ovarian cancer tissue experiments.

For each setting of the SVM consisting of a kernel and diagonal factor (DF), each tissue was classified. Column 2 is the number of features (clones) used. Reported are the number of normal tissues misclassified (FP), tumor tissues misclassified (FN), tumor tissues classified correctly (TP), and normal tissues classified correctly (TN).

Figure 1: SVM classification margins for ovarian tissues. When classifying, the SVM calculates a margin which is the distance of an example from the decision boundary it has learned. In this graph, the margin for each tissue sample calculated using (10) is shown. A positive value indicates a correct classification, and a negative value indicates an incorrect classification. The most negative point corresponds to tissue N039. The second most negative point corresponds to tissue HWBC3.

Dataset	Features	FP	FN	SVM FP	SVM FN
Ovarian(original)	97802	4.6	4.8	5	3
Ovarian(modified)	97802	4.4	3.4	0	0
AML/ALL train	7129	0.6	2.8	0	0
AML treatment	7129	4.8	3.5	3	2
Colon	2000	3.8	3.7	3	3

Table 5: Results for the perceptron on all data sets. The results are averaged over 5 shufflings of the data as this algorithm is sensitive to the order in which it receives the data points. The first column is the dataset used and the second is number of features in the dataset. For the ovarian and colon datasets, the number of normal tissues misclassified (FP) and the number of tumor tissues misclassified (FN) is reported. For the AML/ALL training dataset, the number of AML samples misclassified (FP) and the number of ALL patients misclassified (FN) is reported. For the AML treatment dataset, the number of unsuccessfully treated patients misclassified (FP) and the number of successfully treated patients misclassified (FN) is reported. The last two columns report the best score obtained by the SVM on that dataset.

SVM – General Principles

- SVMs perform binary classification by partitioning the feature space with a surface implied by a subset of the training points (vectors) near the separating surface. These vectors are referred to as **Support Vectors**.
- Efficient with high-dimensional data.
- Solid statistical theory
- Subsume several other methods.

SVM Example (Radial Basis Function)

SVM Ingredients

- Support Vectors
- Mapping from Input Space to Feature Space
- Dot Product - Kernel function
- Weights

Classification of 2-D (Separable) data

Classification of (Separable) 2-D data

Classification of (Separable) 2-D data

- Margin of a point
- Margin of a point set

Classification using the Separator

Perceptron Algorithm (Primal)

Rosenblatt, 1956

Given separable training set S and learning rate $\eta > 0$

$\underline{\mathbf{w}}_0 = \underline{\mathbf{0}}$; // Weight

$b_0 = 0$; // Bias

$k = 0$; $R = \max \|\underline{\mathbf{x}}_i\|$

repeat

for $i = 1$ to N

if $y_i (\underline{\mathbf{w}}_k \bullet \underline{\mathbf{x}}_i + b_k) \leq 0$ **then**

$\underline{\mathbf{w}}_{k+1} = \underline{\mathbf{w}}_k + \eta y_i \underline{\mathbf{x}}_i$

$b_{k+1} = b_k + \eta y_i R^2$

$k = k + 1$

Until no mistakes made within loop

Return k , and $(\underline{\mathbf{w}}_k, b_k)$ where $k = \#$ of mistakes

$$\underline{\mathbf{w}} = \sum a_i y_i \underline{\mathbf{x}}_i$$

Performance for Separable Data

Theorem:

If **margin** m of S is positive, then

$$k \leq (2R/m)^2$$

i.e., the algorithm will always converge,
and will converge quickly.

Perceptron Algorithm (Dual)

Given a separable training set S

$\underline{a} = \underline{0}$; $b_0 = 0$;

$R = \max \|\underline{x}_i\|$

repeat

for $i = 1$ to N

if $y_i (\sum a_j y_j \underline{x}_i \bullet \underline{x}_j + b) \leq 0$ **then**

$a_i = a_i + 1$

$b = b + y_i R^2$

endif

Until no mistakes made within loop

Return (\underline{a}, b)

Non-linear Separators

Main idea: Map into feature space

Figure 2. The idea of SVM machines: map the training data nonlinearly into a higher-dimensional feature space via Φ , and construct a separating hyperplane with maximum margin there. This yields a nonlinear decision boundary in input space. By the use of a kernel function, it is possible to compute the separating hyperplane without explicitly carrying out the map into the feature space.

Non-linear Separators

Useful URLs

- <http://www.support-vector.net>

Perceptron Algorithm (Dual)

Given a separable training set S

$\underline{\mathbf{a}} = \underline{\mathbf{0}}$; $b_0 = 0$;

$R = \max \|\underline{\mathbf{x}}_i\|$

repeat

for $i = 1$ to N

if $y_i (\sum a_j y_j \kappa(\underline{\mathbf{x}}_i, \underline{\mathbf{x}}_j) + b) \leq 0$ **then**

$a_i = a_i + 1$

$b = b + y_i R^2$

Until no mistakes made within loop

Return $(\underline{\mathbf{a}}, b)$

$$\kappa(\underline{\mathbf{x}}_i, \underline{\mathbf{x}}_j) = \Phi(\underline{\mathbf{x}}_i) \cdot \Phi(\underline{\mathbf{x}}_j)$$

Different Kernel Functions

- Polynomial kernel

$$\kappa(X, Y) = (X \bullet Y)^d$$

- Radial Basis Kernel

$$\kappa(X, Y) = \exp\left(\frac{-\|X - Y\|^2}{2\sigma^2}\right)$$

- Sigmoid Kernel

$$\kappa(X, Y) = \tanh(\omega(X \bullet Y) + \theta)$$

SVM Ingredients

- Support Vectors
- Mapping from Input Space to Feature Space
- Dot Product - Kernel function

Generalizations

- How to deal with **more than 2 classes**?
Idea: Associate weight and bias for each class.
- How to deal with **non-linear separator**?
Idea: Support Vector Machines.
- How to deal with **linear regression**?
- How to deal with **non-separable data**?

Applications

- Text Categorization & Information Filtering
 - 12,902 Reuters Stories, 118 categories (91% !!)
- Image Recognition
 - Face Detection, tumor anomalies, defective parts in assembly line, etc.
- Gene Expression Analysis
- Protein Homology Detection

Table 2: Comparison of error rates for various classification methods. Classes are as described in Table 1. The methods are the radial basis function SVM, the SVMs using the scaled dot product kernel raised to the first, second and third power, Parzen windows, Fisher's linear discriminant, and the two decision tree learners, C4.5 and MOC1. The next five columns are the false positive, false negative, true positive and true negative rates summed over three cross-validation splits, followed by the cost, which is the number of false positives plus twice the number of false negatives. These five columns are repeated twice, first using the threshold learned from the training set, and then using the threshold that minimizes the cost on the test set. The threshold optimization is not possible for the decision tree methods, since they do not produce ranked results.

Table 4: Comparison of SVM performance using various kernels. For each of the MYGD classifications, SVMs were trained using four different kernel functions on five different random three-fold splits of the data, training on two-thirds and testing on the remaining third. The first column contains the class, as described in Table 1. The second column contains the kernel function, as described in Table 2. The next five columns contain the threshold-optimized cost (i.e., the number of false positives plus twice the number of false negatives) for each of the five random three-fold splits. The final column is the total cost across all five splits.

Family	Gene	Locus	Error	Description
TCA	YPR001W	CIT3	FN	mitochondrial citrate synthase
	YOR142W	LSC1	FN	α subunit of succinyl-CoA ligase
	YNR001C	CIT1	FN	mitochondrial citrate synthase
	YLR174W	IDP2	FN	isocitrate dehydrogenase
	YIL125W	KGD1	FN	α -ketoglutarate dehydrogenase
	YDR148C	KGD2	FN	component of α -ketoglutarate dehydrogenase complex in mitochondria
	YDL066W	IDP1	FN	mitochondrial form of isocitrate dehydrogenase
	YBL015W	ACH1	FP	acetyl CoA hydrolase
Resp	YPR191W	QCR2	FN	ubiquinol cytochrome-c reductase core protein 2
	YPL271W	ATP15	FN	ATP synthase epsilon subunit
	YPL262W	FUM1	FP	fumarase
	YML120C	ND1	FP	mitochondrial NADH ubiquinone 6 oxidoreductase
	YKL085W	MDH1	FP	mitochondrial malate dehydrogenase
	YDL067C	COX9	FN	subunit VIIa of cytochrome c oxidase
Ribo	YPL037C	EGD1	FP	β subunit of the nascent-polypeptide-associated complex (NAC)
	YLR406C	RPL31B	FN	ribosomal protein L31B (L34B) (YL28)
	YLR075W	RPL10	FP	ribosomal protein L10
	YAL003W	EFB1	FP	translation elongation factor EF-1 β
Prot	YHR027C	RPN1	FN	subunit of 26S proteasome (PA700 subunit)
	YGR270W	YTA7	FN	member of CDC48/PAS1/SEC18 family of ATPases
	YGR048W	UFD1	FP	ubiquitin fusion degradation protein
	YDR069C	DOA4	FN	ubiquitin isopeptidase
	YDL020C	RPN4	FN	involved in ubiquitin degradation pathway
Hist	YOL012C	HTA3	FN	histone-related protein
	YKL049C	CSE4	FN	required for proper kinetochore function

Table 6: Consistently misclassified genes. The table lists all 25 genes that are consistently misclassified by SVMs trained using the MYGD classifications listed in Table 1. Two types of errors are included: a false positive (FP) occurs when the SVM includes the gene in the given class but the MYGD classification does not; a false negative (FN) occurs when the SVM does not include the gene in the given class but the MYGD classification does.

Kernel	DF	Feature	FP	FN	TP	TN
dot-product 0		25	5	4	10	12

Table 1: Error rates for ovarian cancer tissue experiments.

For each setting of the SVM consisting of a kernel and diagonal factor (DF), each tissue was classified. Column 2 is the number of features (clones) used. Reported are the number of normal tissues misclassified (FP), tumor tissues misclassified (FN), tumor tissues classified correctly (TP), and normal tissues classified correctly (TN).

Figure 1: SVM classification margins for ovarian tissues. When classifying, the SVM calculates a margin which is the distance of an example from the decision boundary it has learned. In this graph, the margin for each tissue sample calculated using (10) is shown. A positive value indicates a correct classification, and a negative value indicates an incorrect classification. The most negative point corresponds to tissue N039. The second most negative point corresponds to tissue HWBC3.

Dataset	Features	FP	FN	SVM FP	SVM FN
Ovarian(original)	97802	4.6	4.8	5	3
Ovarian(modified)	97802	4.4	3.4	0	0
AML/ALL train	7129	0.6	2.8	0	0
AML treatment	7129	4.8	3.5	3	2
Colon	2000	3.8	3.7	3	3

Table 5: Results for the perceptron on all data sets. The results are averaged over 5 shufflings of the data as this algorithm is sensitive to the order in which it receives the data points. The first column is the dataset used and the second is number of features in the dataset. For the ovarian and colon datasets, the number of normal tissues misclassified (FP) and the number of tumor tissues misclassified (FN) is reported. For the AML/ALL training dataset, the number of AML samples misclassified (FP) and the number of ALL patients misclassified (FN) is reported. For the AML treatment dataset, the number of unsuccessfully treated patients misclassified (FP) and the number of successfully treated patients misclassified (FN) is reported. The last two columns report the best score obtained by the SVM on that dataset.

SVM Example (Radial Basis Function)

Sources of Variations & Errors in Microarray Data

- Variations in cells/individuals.
- Variations in mRNA extraction, isolation, introduction of dye, variation in dye incorporation, dye interference.
- Variations in probe concentration, probe amounts, substrate surface characteristics
- Variations in hybridization conditions and kinetics
- Variations in optical measurements, spot misalignments, discretization effects, noise due to scanner lens and laser irregularities
- Cross-hybridization of sequences with high sequence identity.
- Limit of factors **Need to Normalize data** results.

Significance Analysis of Microarrays (SAM)

[Tusher, Tibshirani, Chu, PNAS'01]

- Fold change is a typical measure to decide genes of interest.
- However, variations in gene expression are also gene dependent. If **repeats are available**, then such variations can be measured for each gene. This helps to give a better analysis of significant genes of interest.

Genomics

- Study of all genes in a genome, or comparison of whole genomes.
 - Whole genome sequencing
 - Whole genome annotation & Functional genomics
 - Whole genome comparison
 - **PipMaker**: uses BLASTZ to compare very long sequences (> 2Mb); <http://www.cse.psu.edu/pipmaker/>
 - **Mummer**: used for comparing long microbial sequences (uses Suffix trees!)

Genomics (Cont'd)

- Gene Expression

- Microarray experiments & analysis
 - Probe design (**CODEHOP**)
 - Array image analysis (**CrazyQuant**)
 - Identifying genes with significant changes (**SAM**)
 - Clustering

Proteomics

- Study of all **proteins** in a genome, or comparison of whole genomes.
 - Whole genome annotation & Functional proteomics
 - Whole genome comparison
 - Protein Expression: **2D Gel Electrophoresis**

2D Gel Electrophoresis

Other Proteomics Tools

From ExPASy/SWISS-PROT:

- **AACompIdent** identify proteins from aa composition
[Input: aa composition, isoelectric point, mol wt., etc. Output: proteins from DB]
- **AACompSim** compares proteins aa composition with other proteins
- **MultIdent** uses mol wt., mass fingerprints, etc. to identify proteins
- **PeptIdent** compares experimentally determined mass fingerprints with theoretically determined ones for all proteins
- **FindMod** predicts post-translational modifications based on mass difference between experimental and theoretical mass fingerprints.
- **PeptideMass** theoretical mass fingerprint for a given protein.
- **GlycoMod** predicts oligosaccharide modifications from mass difference
- **TGREASE** calculates hydrophobicity of protein along its length

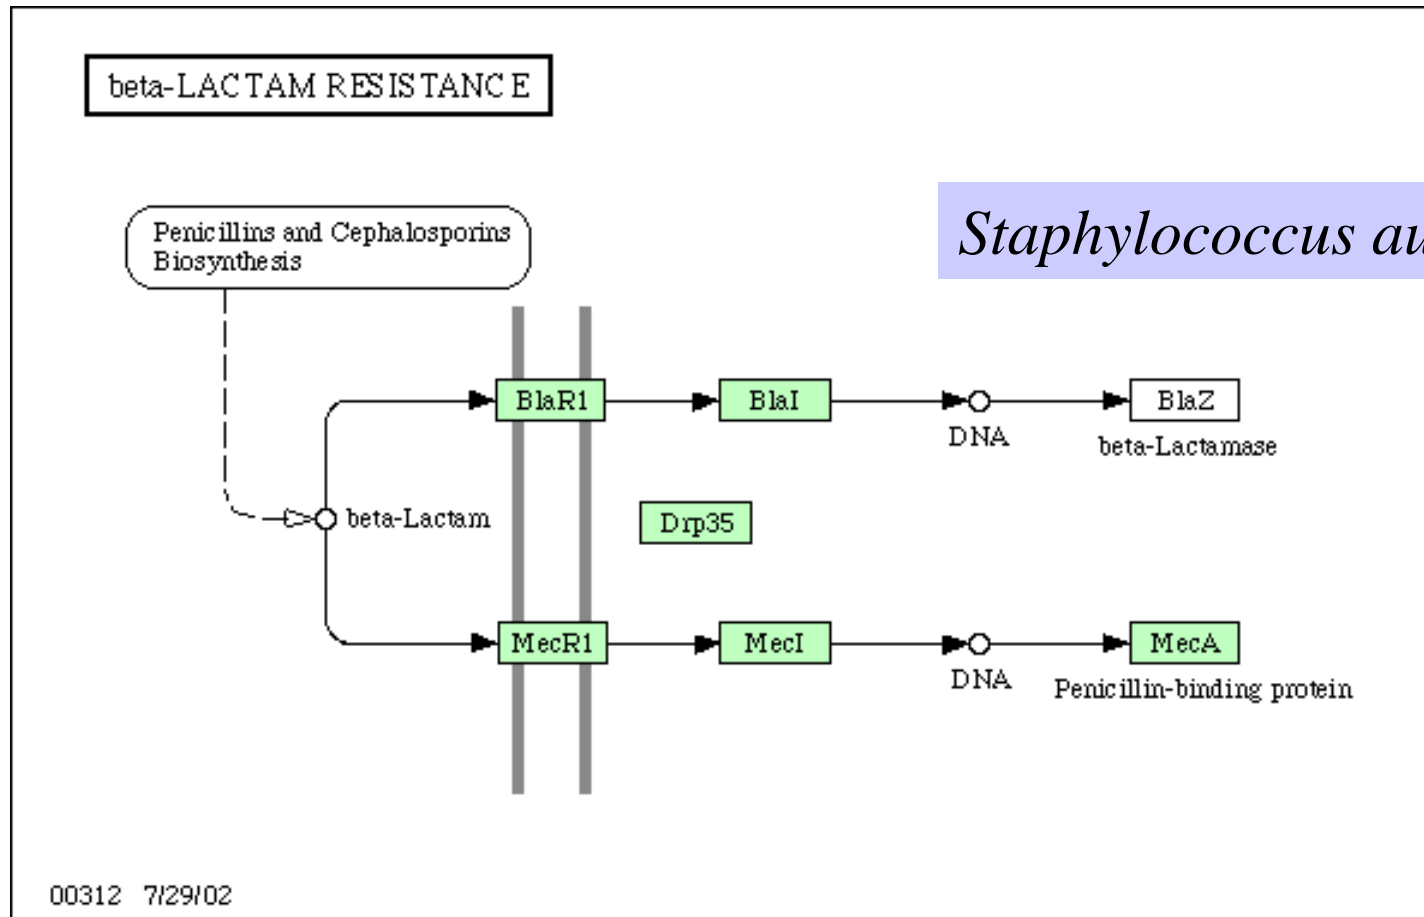

Databases for Comparative Genomics

- PEDANT useful resource for standard questions in comparative genomics. For e.g., *how many known proteins in XXX have known 3-d structures, how many proteins from family YYY are in ZZZ, etc.*
- COGs Clusters of orthologous groups of proteins.
- MBGD Microbial genome database searches for homologs in all microbial genomes

Gene Networks & Pathways

- Genes & Proteins act in concert and therefore form a complex network of dependencies.

Pathway Example from KEGG

Pseudomonas aeruginosa

METHIONINE METABOLISM

STSs and ESTs

- **Sequence-Tagged Site**: short, unique sequence
- **Expressed Sequence Tag**: short, unique sequence from a coding region
 - 1991: 609 ESTs [Adams et al.]
 - June 2000: 4.6 million in **dbEST**
 - Genome sequencing center at St. Louis produce 20,000 ESTs per week.

What Are ESTs and How Are They Made?

- Small pieces of DNA sequence (usually 200 - 500 nucleotides) of low quality.
- Extract mRNA from cells, tissues, or organs and sequence either end. Reverse transcribe to get cDNA (5' EST and 3'EST) and deposit in EST library.
- Used as "**tags**" or markers for that gene.
- Can be used to identify similar genes from other organisms (Complications: variations among organisms, variations in genome size, presence or absence of **introns**).
- 5' ESTs tend to be more useful (cross-species conservation), 3' EST often in UTR.

DNA Markers

- Uniquely identifiable DNA segments.
- Short, <500 nucleotides.
- Layout of these markers give a **map** of genome.
- Markers may be **polymorphic** (variations among individuals). Polymorphism gives rise to **alleles**.
- Found by PCR assays.

Polymorphisms

- Length polymorphisms
 - Variable # of tandem repeats (VNTR)
 - Microsatellites or short tandem repeats
 - Restriction fragment length polymorphism (RFLP) caused by changes in restriction sites.
- Single nucleotide polymorphism (SNP)
 - Average once every ~100 bases in humans
 - Usually biallelic
 - [dbSNP](#) database of SNPs (over 100,000 SNPs)
 - ESTs are a good source of SNPs

SNPs

- SNPs often act as “disease markers”, and provide “genetic predisposition”.
- SNPs may explain differences in drug response of individuals.
- **Association study**: study SNP patterns in diseased individuals and compare against SNP patterns in normal individuals.
- Many diseases associated with SNP profile.
