## **Basic Timestamp Ordering Algorithm**

(Guarantees timestamp order of transaction execution)

Each active database item will have the following two timestamps:

 $read_TS(X)$ : the sequence number of the youngest transaction that read item X.  $write_TS(X)$ : the sequence number of the youngest transaction that wrote item X.

Every transaction is assigned with a unique integer sequence number.  $TS(T_7)$  is the timestamp of  $T_7$  which is the sequence number of the transaction = 7

Consider two transactions  $T_5$  and  $T_8$ , where  $T_8$  has started after  $T_5$ . Hence,  $T_8$  is younger to  $T_5$ . Also,  $TS(T_8) > TS(T_5)$ .

## T<sub>7</sub> requests write\_item(X):

```
If ((read_TS(X) > TS(T<sub>7</sub>)) OR (write_TS(X) > TS(T<sub>7</sub>)))
{
        T<sub>7</sub> will abort; //some younger trans. has read/written X
}
Else
{
        T<sub>7</sub> performs write_item(X);
        write_TS(X) = TS(T<sub>7</sub>);
}
```

## $T_7$ requests read\_item(X):

```
If (write_TS(X) > TS(T<sub>7</sub>))
{
         T<sub>7</sub> will abort; //some younger trans. has written X
}
Else
{
         T<sub>7</sub> performs read_item(X);
         read_TS(X) = max(read_TS(X), TS(T<sub>7</sub>));
}
```
